   - History of Survey Participants
   - Dynamic Agenda Display
   - Publication Of Indicators

4. Conclusion
PostgreSQL has support for ranges of various data types. The common denominator is that the base data type has a clear and unique natural order and that the values being part of a range have no missing values. Natural candidates are date or time related types and numbers as well as its derivates. Specifically PostgreSQL defines following range types:

- INT4RANGE: Range of integer
- INT8RANGE: Range of bigint
- NUMRANGE: Range of numeric
- TSRANGE: Range of timestamp without time zone
- TSTZRANGE: Range of timestamp with time zone
- DATERANGE: Range of date

In this presentation we focus on the last two: DATERANGE and TSTZRANGE.
Typically ranges are represented as a string containing the bounds and an indications if those bounds are included in the range or not. Example using `DATERANGE`:

\[
\begin{array}{cccc}
\text{Infinity} & \text{2012-06-21} & \ldots & \text{2014-10-31} & \text{Infinity} \\
\ldots & \text{-------------} & \text{-------------} & \text{-------------} & \text{-------------} \\
\ldots & \text{----------} & \text{-------------} & \text{-------------} & \text{-------------} \\
\end{array}
\]

Analogue to the first example, you may have one of the bounds empty to create a range with only one open end.
To create a range type you may type cast a text representation of it to the corresponding type or use one of the built-in functions. In both cases the type creation will make sure that your entry is valid.

\[
\text{db=> SELECT } \text{'}\text{[2012-06-21,2014-10-31}\text{]}::\text{DATERANGE;}
\]
\[
\text{[2012-06-21,2014-10-31]}
\]

\[
\text{db=> SELECT daterange(}\text{'}\text{2012-06-21',}'\text{2014-10-31}',\text{'}\text{[}').}
\]
\[
\text{[2012-06-21,2014-10-31]}
\]

\[
\text{db=> SELECT } \text{'}\text{[2015-06-21,2014-10-31]\text{]}::\text{DATERANGE;}
\]
\[
\text{ERROR: range lower bound must be less than or equal to range upper bound}
\]

In the documentation you will find the list of the range type creation functions. General format:

\[
\text{name_of_range_type(lower_bound, upper_bound, bounds);}
\]

lower and upper bound can be NULL for open ends. Bounds is a 2 char string containing the representation of the bounds. If not provided the default is \text{'}\text{[} \text{]}'.
A recommendation: Get used to operate with the default representation of ranges, unless you have a very good reason to do it differently. Consider the following:

```sql
db=> SELECT daterange('2012-06-21','2014-10-30','[)') AS from_function,
       '(2012-06-21,2014-10-30]'::DATERANGE AS from_typecast;
- [ RECORD 1 ]-+------------------------
from_function | [2012-06-22,2014-10-31)
from_typecast | [2012-06-22,2014-10-31)
```

The range creation process returns the default representation if the values are scaled ordinally.

```sql
db=> CREATE TABLE test (dr DATERANGE);
```

```sql
db=> INSERT INTO test VALUES ('(2012-06-21,2014-10-30]'::DATERANGE);
```

```sql
db=> SELECT * FROM test;
- [ RECORD 1 ]----------------
  dr | [2012-06-22,2014-10-31)
```

This can be confusing when you start retrieving the bounding values for whatever operation that you want to perform.
At the time of this writing (Version 9.6.1) range types are supplied with a set of 19 operators. From the official documentation:

- The simple comparison operators <, >, <=, and >= compare the lower bounds first, and only if those are equal, compare the upper bounds. **These comparisons are not usually very useful for ranges, but are provided to allow B-tree indexes to be constructed on ranges.**

- The left-of/right-of/adjacent operators always return false when an empty range is involved; that is, **an empty range is not considered to be either before or after any other range.**

- The union and difference operators **will fail if the resulting range would need to contain two disjoint sub-ranges**, as such a range cannot be represented.
Let’s focus on some range specific operators...

<table>
<thead>
<tr>
<th>Operators</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$A \cap B$</td>
<td>intersection</td>
</tr>
<tr>
<td>$A + B$</td>
<td>union</td>
</tr>
<tr>
<td>$A - B$</td>
<td>difference</td>
</tr>
<tr>
<td>$B - A$</td>
<td>difference</td>
</tr>
<tr>
<td>$A \cap B = true$</td>
<td>overlaps</td>
</tr>
<tr>
<td>$A &lt;&lt; B = true$</td>
<td>$A$ is strictly left of $B$</td>
</tr>
<tr>
<td>$A @&gt; B = true$</td>
<td>$A$ contains $B$</td>
</tr>
<tr>
<td>$A -</td>
<td>!- B = true$</td>
</tr>
</tbody>
</table>
Functions

The built-in functions for range types are helpful to request specific information on the type’s characteristics.

- \( \text{lower}() = 2017-02-25 \)
- \( \text{upper}() = 2017-03-11 \)
- \( \text{lower}_{\text{inc}}() = \text{true} \)
- \( \text{upper}_{\text{inc}}() = \text{false} \)

- \( \text{lower}_{\text{inf}}(\text{anyrange}) , \text{upper}_{\text{inf}}(\text{anyrange}) \): Return a boolean indicating if the requested bound is open ended.
- \( \text{isempty}(\text{anyrange}) \): Return a boolean indicating if the range is empty. Notice that empty is not the same as NULL. In term of DATERANGE, for example, empty means as much as “never”.
- \( \text{merge}(\text{anyrange}, \text{anyrange}) \): The smallest range containing both range arguments. The difference to the union operator (+) it that the range parameters don’t need to be at least contiguous.

4. Conclusion
History of Survey Participants

Rationale

The entries in table `survey_participants` are used to keep track of the information that is required for

- Creating and sending questionnaires or mail invitations (survey name, contact information).
- Sectors and weights for the calculation of macro economic indicators (economic sector, weighting information).

By its nature, contact information is relevant at the moment when mails and questionnaires are sent out. When it comes to the information used for computation, it is clear that we must keep the information that was valid at the time the survey was conducted. We need to know, e.g. how big the company was for any specific day that it delivered survey data.
When you are investigating problems in a database (or mostly in the application built on top of it), you usually want to know exactly who did what and when. In such cases every single change may be relevant to your analysis. This is what we call an audit, i.e. an exact record of all changes in one or more tables.

The KOF surveys are conducted every month and always start at the beginning of a month. If the information about a company is modified many times during a month, e.g. because of mistyped information or follow ups from the company itself, it is not relevant for the survey itself and its analysis. What is important is the information that was valid at the moment when the company was called to attend the survey. To keep record of this specific information is what we call the history of the company.

In short, an audit would record all changes made to a record, while an history keeps track of changes that have an impact on the processes they support. Notice that the history does not even need to be a copy of an existing table. Finally what needs to be kept in the history, again, depends on the processes. An address is relevant at the time of sending out a Questionnaire or an E-Mail. It is not required (at least for us) to keep track of these changes. On the contrary, data used to weigh responses must match the values valid at the time when these responses were delivered.

<td></td>
</tr>
<tr>
<td>validity</td>
<td>tstzrange</td>
<td>not null</td>
</tr>
</tbody>
</table>

Indexes:
- "timeseries_main_pkey" PRIMARY KEY, btree (ts_key, validity)
- "timeseries_main_ts_key_validity_excl"
  EXCLUDE USING gist (ts_key WITH =, validity WITH &&)

```
charles@charles=# SELECT * FROM public.timeseries_main WHERE ts_key = 'kofbarometer';
-[ RECORD 1 ]+-------------------------------------------------------------------
| ts_key  | kofbarometer          |
| ts_data | "2016-11-01"=>"102.162463328593", "2016-12-01"=>"102.161371136933" |
| ts_frequency | 12                  |
| validity | ["2016-12-01 09:00:00+01",) |
```

```
charles@charles=# SELECT (each(ts_data)).* FROM public.timeseries_main
WHERE ts_key = 'kofbarometer';

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2016-11-01</td>
<td>102.162463328593</td>
</tr>
<tr>
<td>2016-12-01</td>
<td>102.161371136933</td>
</tr>
</tbody>
</table>
```
Modify the current valid entry to end at the time of publication.

BEGIN;

UPDATE public.timeseries_main
SET validity = tstzrange(lower(validity), now())
WHERE ts_key = 'kofbarometer'
AND validity @> now();

Create a new current entry accessible from the time of publication.

INSERT INTO public.timeseries_main
SELECT ts_key,
       ts_data || '2017-01-01=>100.00'::HSTORE,
       ts_frequency,
       tstzrange(now(), NULL)
FROM public.timeseries_main
WHERE ts_key = 'kofbarometer'
AND upper(validity) = now();

COMMIT;

For this examples we use now() but in real life you would obviously use a specific timestamp in the future.
We have 2 entries with the same key and and order in time.

```sql
SELECT ts_key, ts_data, validity
FROM public.timeseries_main
WHERE ts_key = 'kofbarometer';
```

Records:

<table>
<thead>
<tr>
<th>ts_key</th>
<th>kofbarometer</th>
</tr>
</thead>
<tbody>
<tr>
<td>ts_data</td>
<td>&quot;2016-11-01&quot; =&gt; 102.162463328593, &quot;2016-12-01&quot; =&gt; 102.161371136933</td>
</tr>
<tr>
<td>validity</td>
<td>[&quot;2016-12-01 09:00:00+01&quot;, &quot;2017-01-03 15:07:40.416938+01&quot;]</td>
</tr>
</tbody>
</table>

```
SELECT (each(ts_data)).*
FROM public.timeseries_main
WHERE ts_key = 'kofbarometer'
AND validity @> clock_timestamp();
```

Keys:

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2016-11-01</td>
<td>102.162463328593</td>
</tr>
<tr>
<td>2016-12-01</td>
<td>102.161371136933</td>
</tr>
<tr>
<td>2017-01-01</td>
<td>100.00</td>
</tr>
</tbody>
</table>

Querying with a time filter only delivers the current entry.
We have seen that filtering is done in the WHERE clause. We can achieve the same result using RLS.

```sql
CREATE POLICY public_access
ON public.timeseries_main
FOR SELECT
TO public
USING (validity @> clock_timestamp());

ALTER TABLE timeseries_main ENABLE ROW LEVEL SECURITY;
```

<table>
<thead>
<tr>
<th>Table &quot;public.timeseries_main&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column</td>
</tr>
<tr>
<td>-----------------</td>
</tr>
<tr>
<td>ts_key</td>
</tr>
<tr>
<td>ts_data</td>
</tr>
<tr>
<td>ts_frequency</td>
</tr>
<tr>
<td>validity</td>
</tr>
</tbody>
</table>

Indexes:
- "timeseries_main_pkey" PRIMARY KEY, btree (ts_key, validity)
- "timeseries_main_ts_key_validity_excl"
  EXCLUDE USING gist (ts_key WITH =, validity WITH &&)

Policies:
- POLICY "public_access" FOR SELECT
  USING ((validity @> clock_timestamp()))
Table owner sees all entries.

```
SELECT CURRENT_USER;
-[ RECORD 1 ]+--------

validity | ['2017-01-03 15:07:40.416938+01",)
```
Any other user without any specific policy defined is public and only sees the currently valid row.

```sql
SET ROLE public_reader;

SELECT CURRENT_USER;
- [ RECORD 1 ]+-------------------
current_user | public_reader

SELECT ts_key, ts_data, validity
FROM public.timeseries_main
WHERE ts_key = 'kofbarometer';

- [ RECORD 1 ]---------------------------------------------------------------
ts_key | kofbarometer
  ts_data | "2016-11-01"=>"102.162463328593", "2016-12-01"=>"102.161371136933",
            | "2017-01-01"=>"100.00"
validity | ["2017-01-03 15:07:40.416938+01",)
Outline

1. Introduction

2. Range Types

3. Use Cases
   - Manage Questionnaires Versions
   - History of Survey Participants
   - Dynamic Agenda Display
   - Publication Of Indicators

4. Conclusion
Conclusions

Date and time based range types offer a solid and flexible solution for a wide variety of needs, including but not limited to:

- Historicize entries for archiving or documentation.
- Create time responsive entries, i.e. decouple database interactions of delivery and consumption.
- Can easily be integrated with capabilities of the database such as indexing.
- They integrate also very well with advanced features like Row Level Security.
