# Intro to PL/R

## What is PL/R?

- R Procedural Language for PostgreSQL. Enables user-defined SQL functions to be written in the R language

## What is R?

- R is an open source (GPL) language and environment for statistical computing and graphics. It is similar to the S language and environment, which was developed at Bell Laboratories by John Chambers and colleagues, and was sold commercially by Insightful Corp. as S-PLUS. R provides a wide variety of statistical (linear and nonlinear modeling, classical statistical tests, time-series analysis, classification, clustering, ...) and graphical techniques, and is highly extensible.

<http://www.r-project.org>

<http://www.joeconway.com/plr>

# Pros

- Leverage people's knowledge and skills
  - statistics is a specialty not common amongst database developers
- Leverage hardware
  - server may be better able to handle large datasets being analyzed
- Processing/bandwidth efficiency
  - why send large datasets across the network?
- Consistency of analysis
  - ensure a particular analysis is done exactly the same once it is vetted
- Abstraction of complexity
  - keep the overall system understandable and maintainable
- Leverage R
  - R has a rich set of core functionality and packages

# Cons

- PostgreSQL user
  - Slower than standard SQL aggregates and PostgreSQL functions for simple cases
  - New language to learn
- R user
  - Debugging more challenging than working directly in R
  - Less flexible for ad hoc analysis

# Installing PL/R

- Installation from source: general steps

```
tar -xzf plr-8.3.0.12.tar.gz
cd plr/
USE_PGXS=1 make
su -c "USE_PGXS=1 make install"
make installcheck
```

- References:

<http://www.joeconway.com/plr/>  
<http://www.joeconway.com/plr/doc/plr-install.html>

# Installing PL/R

- Installation from binary
  - PL/R: Win32, Win64

<http://www.joeconway.com/plr>

- CentOS

```
yum list R-\*  
No Matching Packages
```

- Fedora

```
yum list R-\*  
No Matching Packages
```

- Debian

```
aptitude search '^n plr'
```

# Creating PL/R Functions

- Similar to other PostgreSQL PLs

```
CREATE OR REPLACE FUNCTION func_name(arg-type1 [, arg-type2 ...])
RETURNS return-type AS $$  
    function body referencing arg1 [, arg2 ...]
$$ LANGUAGE 'plr';
```

```
CREATE OR REPLACE FUNCTION func_name(myarg1 arg-type1 [, myarg2 arg-type2 ...])
RETURNS return-type AS $$  
    function body referencing myarg1 [, myarg2 ...]
$$ LANGUAGE 'plr';
```

- But a little different from standard R functions

```
func_name <- function(myarg1 [,myarg2...]) {
    function body referencing myarg1 [, myarg2 ...]
}
```

# Creating PL/R Functions

An alternative method may be used to create a function in PL/R, if certain criteria are met

- Must be a simple call to an existing R function
- Name used for the PL/R function must match that of the R function exactly
- Function may be defined with no body, and the arguments will be passed directly to the R function of the same name

```
CREATE OR REPLACE FUNCTION sd(float8[])
RETURNS float AS '' LANGUAGE 'plr';

SELECT round(sd(ARRAY[1.23,1.31,1.42,1.27])::numeric, 8);
      round
-----
 0.08180261
(1 row)
```

# Argument Type Conversions

- Arguments may be explicitly named when creating a function
- Otherwise argument values are passed as variables arg1 ... argN to the R script
- Define function STRICT to avoid thinking about NULL input values
- In a non-strict function, if the actual value of an argument is NULL, the corresponding argN variable will be set to a NULL R object

# Argument Type Conversions

PostgreSQL Type	R Type
int2, int4	integer
int8, float4, float8, cash, numeric	numeric
bytea	object
everything else	character

- One-dimensional PostgreSQL arrays: converted to multi-element R vectors
  - Pass-by-value integer and numeric types special-cased for performance
- Two-dimensional PostgreSQL arrays: mapped to R matrixes
- Three-dimensional PostgreSQL arrays: converted to three-dimensional R arrays.
- Composite-types are transformed into R data.frames

# Return Type Conversions

- Return values are special-cased for performance if
  - R data type is Integer or Real
  - PostgreSQL type is 1D array of pass-by-value numeric
  - no NULL/NA elements
- Scalar bytea return values are also special-cased
  - R object being returned is serialized
  - Binary result directly mapped into PostgreSQL bytea
- Otherwise return values are first coerced to R character
  - If resulting string is acceptable for PostgreSQL return type, will produce a result

# Return Type Conversions

- To return a NULL value from a PL/R function, return NULL

```
CREATE OR REPLACE FUNCTION r_max (integer, integer)
RETURNS integer AS $$%
    if (is.null(arg1) && is.null(arg2))
        return(NULL)
    if (is.null(arg1))
        return(arg2)
    if (is.null(arg2))
        return(arg1)
    if (arg1 > arg2)
        return(arg1)
    arg2
$$ LANGUAGE 'plr';
```

# Return Type Conversions

- Data type similar to arguments
- Mapping between the dimensionality of the declared PostgreSQL return type and the type of R object
- Depends on both R object dimensions as well declared PostgreSQL dimensions (i.e. scalar, array, composite type)
  - if return value in PL/R function is a data.frame, and Postgres return type is setof composite, the data frame is returned as rows and columns
  - if R = 1, 2, or 3D array, and Postgres = array, then return is array

# Return Type Conversions

PgSQL return type	R type	Result
scalar	array, matrix, vector	first column of first row
setof scalar	1D array, greater than 2D array, vector	multi-row, 1 column set
scalar	data.frame	textual representation of the first column's vector
setof scalar	2D array, matrix, data.frame	#columns > 1, error #columns == 1, multi-row, 1 column set
array	1D array, greater than 3D array, vector	1D array
array	2D array, matrix, data.frame	2D array
array	3D array	3D array
composite	1D array, greater than 2D array, vector	first row, 1 column
setof composite	1D array, greater than 2D array, vector	multi-row, 1 column set
composite	2D array, matrix, data.frame	first row, multi-column
setof composite	2D array, matrix, data.frame	multi-row, multi-column set

# SQL Queries

```
pg.spi.exec(character query)
```

- Execute SQL query given as a string
- Error in the query causes an error to be raised
- Returns number of rows processed for INSERT, UPDATE, or DELETE statements
- Returns zero if the query is a utility statement
- SELECT statement, the values of the selected columns are placed in an R data.frame with the target column names used as the frame column names
- Non-numeric columns are not converted to R "factors". If you want all non-numeric columns converted to factors, a convenience function pg.spi.factor is provided.

# SQL Queries

```
CREATE OR REPLACE FUNCTION test_spi_tup(text)
RETURNS SETOF RECORD AS $$$
    pg.spi.exec(arg1)
$$ language 'plr';

SELECT * FROM test_spi_tup($$*
    SELECT oid,
        NULL::text as nullcol,
        typename
    FROM pg_type
    WHERE typename = 'oid'
    OR typename = 'text'
$$)
AS t(typeid oid, nullcol text, typename name);
typeid | nullcol | typename
-----+-----+
  25 |         | text
  26 |         | oid
(2 rows)
```

# Prepared SQL

```
load_r_typenames()  
pg.spi.prepare(character query, integer vector type_vector)  
pg.spi.execp(external pointer saved_plan, variable listvalue_list)
```

- `load_r_typenames()` used to make predefined PostgreSQL data type global variables available
- `pg.spi.prepare()` prepares and saves a query plan for later execution
- `pg.spi.execp()` executes previously prepared query
- `saved_plan` is the external pointer returned by `pg.spi.prepare`
- If query references arguments, `value_list` must be supplied:  
this is an R list of actual values for the plan arguments
  - Must be the same length as the argument `type_vector` previously given to `pg.spi.prepare`
  - Pass NA for `value_list` if the query has no arguments

# Prepared SQL

```
SELECT load_r_typenames();

CREATE OR REPLACE FUNCTION test_spi_prep(text)
RETURNS TEXT AS $$
    sp <- pg.spi.prepare(arg1, c(NAMEOID, NAMEOID));
    print("OK");
$$ language 'plr';

SELECT test_spi_prep('SELECT oid, typname
                      FROM pg_type
                      WHERE typname = $1 OR typname = $2');

CREATE OR REPLACE FUNCTION test_spi_execp(text, text, text)
RETURNS SETOF RECORD AS $$
    pg.spi.execp(pg.reval(arg1), list(arg2,arg3))
$$ language 'plr';

SELECT * FROM test_spi_execp('sp','oid','text')
AS t(typeid oid, typename name);
    typeid | typename
-----+-----
        25 | text
        26 | oid
(2 rows)
```

# Cursors

```
pg.spi.cursor_open(character cursor_name, external pointer saved_plan, variable list value_list)
pg.spi.cursor_fetch(external pointer cursor, boolean forward, integer rows)
pg.spi.cursor_close(external pointercursor)
```

- `pg.spi.cursor_open()` opens a cursor identified by `cursor_name`, used to scroll through the results of query plan previously prepared by `pg.spi.prepare`
- `pg.spi.cursor_fetch()` fetches rows from the cursor object
- `pg.spi.cursor_close()` closes previously opened cursor

# Utility

```
pg.quoteliteral(character SQL_string)
pg.quoteident(character SQL_string)
pg.thrownotice(character message)
pg.throwerror(character message)
pg.spi.factor(data.frame data)
```

- pg.quoteliteral() safely quotes string literals
- pg.quoteident () quotes string to be used as an identifier
- pg.thrownotice() and pg.throwerror() emit PostgreSQL NOTICE or ERROR message
- pg.spi.factor() accepts an R data.frame as input, and converts all non-numeric columns to factors

# RPostgreSQL Compatibility

```
dbDriver(character dvr_name)
dbConnect(DBIDriver drv, character user, character password,
          character host, character dbname, character port,
          character tty, character options)
dbSendQuery(DBIConnection conn, character sql)
fetch(DBIResult rs, integer num_rows)
dbClearResult (DBIResult rs)
dbGetQuery(DBIConnection conn, character sql)
dbReadTable(DBIConnection conn, character name)
dbDisconnect(DBIConnection conn)
dbUnloadDriver(DBIDriver drv)
```

- Allows function to be first prototyped using an R client, then moved to PL/R for production use
- Nominally work like their RPostgreSQL counterparts except that all queries are performed in the current database
- Driver and connection related parameters are ignored, and dbDriver, dbConnect, dbDisconnect, and dbUnloadDriver are no-ops

# RPostgreSQL Compatibility Example

- PostgreSQL access from R

```
require(TSP)
require(fields)
require(RPostgreSQL)

drv <- dbDriver("PostgreSQL")
conn <- dbConnect(drv, user="postgres", dbname="pgissc")

sql.str <- "select id, st_x(location) as x, st_y(location) as y, location from stands;"
waypts <- dbGetQuery(conn, sql.str)
dist.matrix <- rdist.earth(waypts[,2:3], R=3949.0)
rtsp <- TSP(dist.matrix)
soln <- solve_TSP(rtsp)
tour <- as.vector(soln)

dbDisconnect(conn)
dbUnloadDriver(drv)
print(paste("tour.dist=", attributes(soln)$tour_length))

[1] "tour.dist= 2804.58129355858"
```

# RPostgreSQL Compatibility Example

- Same function from PL/R

```
CREATE OR REPLACE FUNCTION tsp_tour_length() RETURNS float8 AS
$$
require(TSP)
require(fields)
require(RPostgreSQL)

drv <- dbDriver("PostgreSQL")
conn <- dbConnect(drv, user="postgres", dbname="pgissc")

sql.str <- "select id, st_x(location) as x, st_y(location) as y, location from stands;"
waypts <- dbGetQuery(conn, sql.str)
dist.matrix <- rdist.earth(waypts[,2:3], R=3949.0)
rtsp <- TSP(dist.matrix)
soln <- solve_TSP(rtsp)

dbDisconnect(conn)
dbUnloadDriver(drv)
return(attributes(soln)$tour_length)
$$
LANGUAGE 'plr' STRICT;

SELECT tsp_tour_length();
tsp_tour_length
-----
2804.58129355858
(1 row)
```

# State Variable

- Global R variable called pg.state.firstpass
- TRUE first time PL/R function called for particular query
- On subsequent calls value is left unchanged
- Allows PL/R function to perform expensive initialization on the first call, reuse the results for the remaining rows

```
CREATE TABLE t (f1 int);
INSERT INTO t VALUES (1),(2),(3);
CREATE OR REPLACE FUNCTION state(INT) RETURNS INT AS $$%
if (pg.state.firstpass == TRUE)
{pg.state.firstpass <- FALSE; Sys.sleep(10); return(arg1)}
else {return(arg1)}
$$ LANGUAGE plr;

\timing
SELECT f1, state(f1) FROM t;
 f1 | state
----+-----
 1 |    1
 2 |    2
 3 |    3
(3 rows)
```

Time: 10003.472 ms

# Preloading PL/R Shared Object

- postgresql.conf variable `shared_preload_libraries` specifies one or more shared libraries to be preloaded and initialized at server start
- If more than one library is to be loaded, separate their names with commas
- This parameter can only be set at server start
- Library startup time is avoided when the library is first used
- On Windows hosts, preloading a library at server start will not reduce startup time
- If specified library not found, the server will fail to start

```
shared_preload_libraries = '$libdir/plr'
```

# Auto-loading R code

- Special table, `plr_modules`, presumed to contain R functions
- If table exists, functions fetched and loaded into R interpreter on initialization
- `plr_modules` defined as follows

```
CREATE TABLE plr_modules (
    modseq int4,
    modsrd text
);
```

- `modseq` used to control order of installation
- `modsrd` contains text of R code to be executed
- `plr_modules` must be readable by all, but it is wise to make it owned and writable only by the database administrator
- Use `reload_plr_modules()` to force re-loading `plr_modules`

# Auto-loading R code Example

## EXAMPLE

- Create R function named pg.test.module.load on initialization
- PL/R function may now simply reference the function directly

```
INSERT INTO plr_modules
    VALUES (0, 'pg.test.module.load <-function(msg) {print(msg)}');
SELECT reload_plr_modules();

CREATE OR REPLACE FUNCTION pg_test_module_load(TEXT) RETURNS TEXT AS $$
    pg.test.module.load(arg1)
$$ language 'plr';

SELECT pg_test_module_load('hello world');
pg_test_module_load
-----
hello world
(1 row)
```

# Interactively Loading R Code

```
install_rcmd(text R_code)
```

- `install_rcmd()` installs R code, given as a string, into the interpreter
- Global status data held between calls or shared between different PL/R functions
- Persists for the duration of the SQL client connection

```
SELECT install_rcmd('pg.test.install <-function(msg) {print(msg)}');
```

---

```
install_rcmd
-----
OK
(1 row)
```

```
CREATE OR REPLACE FUNCTION pg_test_install(TEXT) RETURNS TEXT AS $$  
    pg.test.install(arg1)  
$$ language 'plr';
```

```
SELECT pg_test_install('hello world');  
pg_test_install
-----
hello world
(1 row)
```

# Array

```
plr_singleton_array(float8 first_element)
plr_array_push(float8[] array, float8 next_element)
plr_array_accum(float8[] state_value, float8 next_element)
```

- `plr_singleton_array()` creates a new PostgreSQL array using `first_element`
- `plr_array_push()` pushes a new element onto the end of an existing PostgreSQL array
- `plr_array_accum()` creates new array using `next_element` if `state_value` is `NULL`, otherwise, pushes `next_element` onto the end of `state_value`
- C functions that implement these PostgreSQL functions are capable of accepting and returning other data types
- These are somewhat redundant with built in functionality of recent PostgreSQL releases

# Array Example

```
CREATE OR REPLACE FUNCTION array_accum (int[], int)
RETURNS int[]
AS '$libdir/plr','plr_array_accum'
LANGUAGE 'C';

SELECT array_accum(NULL, 42);
array_accum
-----
{42}
(1 row)
SELECT array_accum(ARRAY[23,35], 42);
array_accum
-----
{23,35,42}
(1 row)
```

# Utility

```
load_r_typenames()  
r_typenames()  
plr_set_display(text display)  
plr_get_raw(bytea serialized_object)
```

- `load_r_typenames()` installs datatype Oid variables into the R interpreter as globals
- `r_typenames()` displays the datatype Oid variables
- `plr_set_display()` sets the DISPLAY environment variable under which the Postmaster is currently running
- `plr_get_raw()` unserializes R object and returns the pure raw bytes –e.g. object being returned is JPEG or PNG graphic

# Environment

```
plr_environ()
```

- `plr_environ()` displays environment under which the Postmaster is currently running
- Useful to debug issues related to R specific environment variables
- Installed with EXECUTE permission revoked from PUBLIC

```
SELECT * FROM plr_environ() WHERE name = 'PGDATA';
   name |          value
-----+-----
 PGDATA | /usr/local/pgsql-REL8_4_STABLE/data
(1 row)
```

# Aggregates

- Aggregates in PostgreSQL are extensible via SQL commands
- State transition function and possibly a final function are specified
- Initial condition for state function may also be specified

# Aggregates Example

## EXAMPLE

```
CREATE OR REPLACE FUNCTION r_median(ANYARRAY) RETURNS ANYELEMENT AS $$  
    median(arg1)  
$$ LANGUAGE 'plr';  
  
CREATE AGGREGATE median (ANYELEMENT)  
(  
    sfunc = array_append,  
    stype = anyarray,  
    finalfunc = r_median,  
    initcond = '{}'  
);  
  
CREATE TABLE FOO(f0 int, f1 text, f2 float8);  
INSERT INTO foo VALUES (1,'cat1',1.21), (2,'cat1',1.24), (3,'cat1',1.18),  
                      (4,'cat1',1.26), (5,'cat1',1.15), (6,'cat2',1.15),  
                      (7,'cat2',1.26), (8,'cat2',1.32), (9,'cat2',1.30);  
  
SELECT f1, median(f2) FROM foo GROUP BY f1 ORDER BY f1;  
   f1 | median  
-----+-----  
 cat1 |  1.21  
 cat2 |  1.28  
(2 rows)
```

# Aggregates Example

## EXAMPLE

```
CREATE OR REPLACE FUNCTION r_quartile(anyarray) RETURNS anyarray AS $$  
    quantile(arg1, probs = seq(0, 1, 0.25), names = FALSE)  
$$ LANGUAGE 'plr';  
  
CREATE AGGREGATE quartile (ANYELEMENT)  
(  
    sfunc = array_append,  
    stype = anyarray,  
    finalfunc = r_quantile,  
    initcond = '{}'  
);  
  
SELECT workstation, quartile(id_val) FROM sample_numeric_data  
WHERE ia_id = 'G121XB8A' GROUP BY workstation;  
workstation | quartile  
-----+-----  
1055 | {4.19,5.02,5.21,5.5,6.89}  
1051 | {3.89,4.66,4.825,5.2675,5.47}  
1068 | {4.33,5.2625,5.455,5.5275,6.01}  
1070 | {4.51,5.1975,5.485,5.7575,6.41}  
(4 rows)
```

# Aggregates Example - Quartile Boxplot Output

# Triggers

- Triggers can be written in PL/R
- Function called as a trigger must have no arguments and return type TRIGGER
- NULL return silently suppresses the triggering operation for this row
- One row data.frame returned is inserted instead of the one given in pg.tg.new (BEFORE, FOR EACH ROW only)
- Info from trigger manager passed to PL/R function in variables

# Trigger Variables

- pg.tg.name - name of the trigger
- pg.tg.relid - object ID of table invoking trigger
- pg.tg.relname - name of table invoking trigger
- pg.tg.when - BEFORE or AFTER (trigger type)
- pg.tg.level - ROW or STATEMENT (trigger type)
- pg.tg.op - INSERT, UPDATE, or DELETE
- pg.tg.new/pg.tg.old - NEW and OLD rows
- pg.tg.args - vector of arguments given in CREATE TRIGGER

# Trigger Example

## EXAMPLE

```
CREATE FUNCTION trigfunc_modcount() RETURNS trigger AS $$

    if (pg.tg.op == "INSERT")
    {
        retval <- pg.tg.new
        retval[pg.tg.args[1]] <- 0
    }
    if (pg.tg.op == "UPDATE")
    {
        retval <- pg.tg.new
        retval[pg.tg.args[1]] <- pg.tg.old[pg.tg.args[1]] + 1
    }
    if (pg.tg.op == "DELETE")
        retval <- pg.tg.old

    return(retval)
$$ LANGUAGE plr;

CREATE TABLE mytab (num integer, description text, modcnt integer);

CREATE TRIGGER trig_mytab_modcount
BEFORE INSERT OR UPDATE ON mytab
FOR EACH ROW
EXECUTE PROCEDURE trigfunc_modcount('modcnt');
```

# Geospatial Example

- Solve the famous Traveling Salesman Problem
  - Given list of location and distances, find a shortest possible tour that visits each location exactly once
- NP-hard problem in combinatorial optimization
- Applications include, for example:
  - Logistics
  - Land management
  - Semiconductor inspection
  - Genome sequencing
  - Routing of SONET rings

[http://en.wikipedia.org/wiki/Travelling\\_salesman\\_problem](http://en.wikipedia.org/wiki/Travelling_salesman_problem)

<http://www.tsp.gatech.edu/apps/index.html>

# Geospatial Example

- Create and populate table with locations

```
CREATE TABLE stands (id serial primary key,
                     strata integer not null,
                     initage integer);
SELECT AddGeometryColumn('', 'stands', 'boundary', '4326', 'MULTIPOLYGON', 2);
CREATE INDEX "stands_boundary_gist" ON "stands" USING gist ("boundary" gist_geometry_ops);
SELECT AddGeometryColumn('', 'stands', 'location', '4326', 'POINT', 2);
CREATE INDEX "stands_location_gist" ON "stands" USING gist ("location" gist_geometry_ops);

INSERT INTO stands (id,strata,initage,boundary,location) VALUES
(1,1,1,GeometryFromText('MULTIPOLYGON(((59.250000 65.000000,55.000000 65.000000,55.000000 51.750000,
60.735294 53.470588, 62.875000 57.750000, 59.250000 65.000000 )))', 4326),
 GeometryFromText('POINT( 61.000000 59.000000 )', 4326 ))
,(2,2,1,GeometryFromText('MULTIPOLYGON(((67.000000 65.000000,59.250000 65.000000,62.875000 57.750000,
67.000000 60.500000, 67.000000 65.000000 )))', 4326),
 GeometryFromText('POINT( 63.000000 60.000000 )', 4326 ))
,(3,3,1,GeometryFromText('MULTIPOLYGON(((67.045455 52.681818,60.735294 53.470588,55.000000 51.750000,
55.000000 45.000000, 65.125000 45.000000, 67.045455 52.681818 )))', 4326),
 GeometryFromText('POINT( 64.000000 49.000000 )', 4326 ))
;
```

# Geospatial Example

- Create and populate table with locations

```
INSERT INTO stands (id,strata,initage,boundary,location) VALUES
(4,4,1,GeometryFromText('MULTIPOLYGON(((71.500000 53.500000,70.357143 53.785714,67.045455 52.681818,
65.125000 45.000000, 71.500000 45.000000, 71.500000 53.500000 )))', 4326),
GeometryFromText('POINT( 68.000000 48.000000 )', 4326 ))
,(5,5,1,GeometryFromText('MULTIPOLYGON(((69.750000 65.000000,67.000000 65.000000,67.000000 60.500000,
70.357143 53.785714, 71.500000 53.500000, 74.928571 54.642857, 69.750000 65.000000 )))', 4326),
GeometryFromText('POINT( 71.000000 60.000000 )', 4326 ))
,(6,6,1,GeometryFromText('MULTIPOLYGON(((80.000000 65.000000,69.750000 65.000000,74.928571 54.642857,
80.000000 55.423077, 80.000000 65.000000 )))', 4326),
